Understanding Microbial Biomass: The Foundation of Terrestrial Ecosystems

What Is Microbial Biomass?

Microbial biomass refers to the total mass of all living microorganisms—bacteria, fungi, archaea, protozoa, and viruses—present within a specific soil volume or mass. Although microscopic, these organisms collectively constitute a significant component of soil organic matter, influencing nutrient availability, organic matter decomposition, and soil structure.

Key points about microbial biomass:

Understanding terrestrial biomes is essential for grasping how life adapts to different environmental conditions and how these ecosystems function and interact. This review aims to explore the major types of terrestrial biomes, their characteristics, the flora and fauna that inhabit them, and the importance of conserving these vital ecosystems.

Overview of Terrestrial Biomes

Terrestrial biomes are large geographical areas characterized by specific climatic conditions, soil types, plant communities, and animal populations. These biomes are shaped primarily by temperature, precipitation, and other environmental factors that influence the types of organisms that can survive there.

Types of Terrestrial Biomes

There are several major terrestrial biomes, each with unique features and biodiversity. The most recognized biomes include forests, grasslands, deserts, tundra, and mountainous regions.

Forests

Forests are dense collections of trees and other vegetation, covering about 31% of the Earth's land surface. They are classified into several subtypes:

- **Tropical Rainforests:** Found near the equator, these forests receive high rainfall and maintain warm temperatures year-round. They are incredibly biodiverse, hosting more species of plants and animals than any other biome.
- **Temperate Forests:** Located in regions with moderate climate, these forests experience distinct seasons and have deciduous trees that shed leaves annually.
- **Boreal Forests (Taiga):** Found in northern latitudes, boreal forests are dominated by coniferous trees and experience long, cold winters.

Grasslands

Grasslands are open landscapes dominated by grasses, with few trees or shrubs. They occur in regions with moderate rainfall that is insufficient to support forests.

- **Temperate Grasslands:** Found in North America (prairies), Eurasia (steppes), and South America (pampas). They support large herbivores like bison and antelope.
- **Tropical Grasslands (Savannas):** Characterized by seasonal rainfall and scattered trees, savannas are typical in Africa, Australia, and South America and are home to animals like elephants and lions.
