**Question** What is the difference between Gram-positive and Gram-negative bacteria? Gram-positive bacteria have thick peptidoglycan cell walls that retain the crystal violet stain, appearing purple under the microscope. In contrast, Gram-negative bacteria have thinner peptidoglycan layers and an outer membrane, which do not retain the crystal violet stain and are counterstained pink by safranin. **What are the main functions of bacterial capsules?** Bacterial capsules protect the bacteria from phagocytosis by host immune cells, help in adherence to surfaces, prevent desiccation, and contribute to pathogenicity. **How do antibiotics target bacterial cell walls?** Certain antibiotics, such as penicillins and cephalosporins, inhibit the synthesis of peptidoglycan, an essential component of bacterial cell walls, leading to cell lysis and death, particularly in actively dividing bacteria. **What is the significance of bacterial conjugation?** Bacterial conjugation is a process of horizontal gene transfer where genetic material, usually a plasmid, is transferred from one bacterium to another through direct contact, facilitating the spread of antibiotic resistance and virulence factors. **Which microorganisms are classified as obligate aerobes?** Obligate aerobes are microorganisms that require oxygen for growth, such as *Mycobacterium tuberculosis* and *Pseudomonas aeruginosa*. **What role do microbiota play in human health?** Human microbiota

assist in digestion, synthesize vitamins, prevent colonization by pathogens, and modulate the immune system, thus playing a crucial role in overall health. What are the primary methods used for sterilization in microbiology laboratories? Common sterilization methods include autoclaving (steam under pressure), dry heat sterilization, filtration, chemical sterilants like ethylene oxide, and irradiation, all aimed at eliminating all forms of microbial life.
