- FM (Frequency Modulation) Synthesis: Uses one waveform (carrier) modulated by another (modulator) to produce complex, often metallic or bell-like sounds.
- Wavetable Synthesis: Plays back a series of pre-recorded waveforms, allowing for dynamic timbral changes.
- Granular Synthesis: Breaks sound into tiny grains and manipulates them to produce textures and noise.

While each method has its unique approach, this guide primarily focuses on how to generate noise?an essential element across many synthesis techniques.

Understanding Noise in Synthesis

In audio, noise refers to a sound that contains a broad spectrum of frequencies, with no distinct pitch or harmonic structure. It?s used in various contexts, from creating atmospheric textures and percussion sounds to adding realism in sound effects.

Types of Noise

- White Noise: Contains equal energy across all frequencies, resulting in a bright, hissing sound.

Shaping Noise: Filters, Envelopes, and Modulation

Generating noise alone is just the start. The real artistry lies in shaping that raw sound into something musically and creatively useful.

Filtering Noise

Filters are the primary tools for sculpting noise.

- High-pass filter (HPF): Removes low frequencies, emphasizing the higher spectrum.

Envelopes

An envelope defines how a sound evolves over time—attack, decay, sustain, and release (ADSR).

- Applying an envelope to noise: Creates dynamic textures, such as a sudden burst or a gradual fade.
- Example: Short attack and decay with no sustain produce a quick "snap," useful for percussion or sound effects.

Modulation

Modulation involves changing parameters over time, adding movement and complexity.

- LFO (Low-Frequency Oscillator): Can modulate filter cutoff, amplitude, or pitch of noise for vibrato, tremolo, or rhythmic effects.
